SUMMARY AND EXPLANATION

Mumps is an acute, generally self-limiting, contagious disease with moderate fever of short duration. Bilateral or unilateral parotitis is the most common clinical feature. Secondary involvement concerns the testes, ovaries, central nervous system and, more rarely, the pancreas, peripheral nerves, eye, inner ear and other organs.

The incubation period for Mumps Virus ranges between 18 and 21 days. Infections are spread by droplets via the upper respiratory route. Between 25 and 50 percent of all infections are silent. Immunity after infection appears to be lifelong; however, silent reinfections may occur although it is probably an infrequent event. An attenuated live virus vaccine is available which induces lower levels of measurable antibody than natural infection.

Only one distinct antigenic type of Mumps Virus is known. Some antigenic cross-reactivity and anamnestic antibody responses exist with other Paramyxoviruses, particularly Parainfluenza Type 1, in some serological tests. However, cross-reacting antibodies do not appear to be a problem when testing for Mumps Virus antibody by immunofluorescence. Paired serum samples should be used for serological analysis, and the initial specimen should be obtained as early as possible after the onset of symptoms. IgG antibodies appear within the first week, reach high titers, and persist as protective antibody for apparent lifelong immunity.

Even though traditional serologic diagnosis of Mumps requires the identification of a significant (fourfold or greater) rise in IgG antibody titer between acute and convalescent phase sera, a diagnosis can also be made by the demonstration of the presence of IgM antibody in a single specimen. Correct interpretation of serologic data depends upon the proper timing of specimen collection in relation to onset of symptoms. Timing is especially important for interpreting negative IgM results. Studies have shown that infection with Mumps Virus results in the detection of IgM antibody within 2 to 4 days following the onset of clinical symptoms, peak at 1 to 2 weeks, persist for about 3 months and are rarely detectable as long as 6 months after infection. Therefore, single specimens collected within 10 to 15 days after onset are useful for the identification of virus specific immunoglobulin M (IgM).

Many tests for the determination of antibodies to Mumps Virus have been described. The traditional assays of viral neutralization, hemagglutination inhibition (HI), and complement fixation (CF) all have the drawbacks of either being too cumbersome for routine serological work, or have shortcomings with regard to sensitivity and reliability. Both CF and HI suffer from a relatively low sensitivity, and cross-reacting antibodies to other Paramyxoviruses may pose a problem. Both immunofluorescence and ELISA tests have the advantages of being sensitive and capable of allowing the separate identification of IgG and IgM viral antibodies for both determination of immune status and diagnosis of acute infection.
PRINCIPLE OF THE IFA PROCEDURE

The MBL Bion MUMPS-G ANTIBODY TEST SYSTEM utilizes the indirect fluorescent antibody assay method first described by Weller and Coons and further developed by Riggs, et al. The procedure is carried out in two basic reaction steps:

Step 1 - Human serum is reacted with the antigen substrate. Antibodies, if present, will bind to the antigen forming stable antigen-antibody complexes. If no antibodies are present, the complexes will not be formed and serum components will be washed away.

Step 2 - Fluorescein labeled antihuman IgG antibody is added to the reaction site which binds with the complexes formed in step one. This results in a positive reaction of bright apple-green fluorescence when viewed with a properly equipped fluorescence microscope. If no complexes are formed in step one, the fluorescein labeled antibody will be washed away, exhibiting a negative result.

REAGENTS

MUMPS VIRUS ANTIGEN SUBSTRATE SLIDES

Ten individually foil-wrapped twelve slides with a mixture of Mumps (CDC Strain) infected and uninfected HEp-2 cells fixed onto each well. Each well contains an average of 10-50% infected cells per 200X field. Stable in sealed foil pouch at 8°C, or lower, until labeled expiration date.

POSITIVE CONTROL SERUM

One vial containing 0.5 ml Mumps positive IgG human control serum with protein stabilizer and 0.005% thimerosal. Stable at 2-8°C until labeled expiration date.

NEGATIVE CONTROL SERUM

One vial containing 0.5 ml Mumps negative human control serum with protein stabilizer and 0.005% thimerosal. Stable at 2-8°C until labeled expiration date.

MOUNTING MEDIUM

One dropper vial containing 3.5 ml phosphate buffered glycerol of pH 7.4 ± 0.2. Stable at 2-8°C until labeled expiration date.

FLUORESCENT ANTIBODY CONJUGATE

Two ready to use dropper vials, each containing 3.5 ml fluorescein isothiocyanate labeled goat antihuman IgG (heavy chain specific) with 0.01% Evans Blue counterstain, protein stabilizer, less than 0.1% sodium azide and 0.001% thimerosal added. Stable at 2-8°C away from direct light until labeled expiration date.

PHOSPHATE BUFFERED SALINE (PBS)

Two one-liter packets of dry PBS. Stable in sealed packet at 25°C, or lower, until labeled expiration date.

BUFFER PREPARATION

Place contents of a one-liter PBS packet into a one-liter volumetric flask, add *distilled water to the one-liter mark, mix and leave several hours or overnight to dissolve. Reconstituted buffer should have a pH of 7.4 ± 0.2. Adjust with 1N NaOH or 1N HCL if pH value is outside the stated range. Store in a clean screw capped bottle at 25°C or lower. Stable until labeled expiration date provided no gross contamination is seen. Do not use if pH changes, if the solution turns cloudy, or if a precipitate forms.

* Use deionized water with caution, as pH of this type of water may vary causing the pH of PBS to become unstable upon prolonged storage.

WARNINGS AND PRECAUTIONS

1. For in vitro diagnostic use.
2. The antigenic substrates have been fixed in acetone and contain no detectable live Mumps Virus. However, they should be handled and disposed of as any potentially biohazardous laboratory material.
3. Do not remove slides from pouches until ready for testing. Do not use if pouch has been punctured, as indicated by a flat pouch.
4. All reagents should be brought to room temperature (20-25°C) prior to use.
5. Abnormal test results may be seen if the antigen substrate slides are allowed to dry during the staining procedure.
6. Refrigeration (2-8°C) of kit immediately upon arrival will insure stability until labeled expiration date.
7. Reagents should not be used beyond stated expiration date.
8. Substitution of components other than those provided may yield inconsistent results.
9. Avoid microbial contamination of all reagents involved in the testing procedure or incorrect results may occur.
10. Incubation times or temperatures other than those specified may give erroneous results.
11. Reusable glassware must be washed and thoroughly rinsed free of detergents.
12. Care should be taken to avoid splashing and generation of aerosols.
13. Do not expose conjugate to strong light during storage or use.
14. Previously frozen specimens after thawing should be thoroughly mixed prior to testing. It is recommended that sera freeze thawed no more than one time. If repeated testing is required, it is suggested that specimen be aliquoted.
15. Patient samples, as well as all materials coming into contact with them, should be handled at the Biosafety Level 2 as recommended for any potentially infectious human serum or blood specimen in the CDC/NIH manual “Biosafety in Microbiological and Biomedical Laboratories”, 1984 Edition. Never pipette by mouth. Avoid contact with skin and mucous membranes.
**SPECIMEN COLLECTION**

Blood should be collected fasting or at least one hour after meals to avoid lipemic serum, as excess lipids may produce a “film” over the substrate. Aseptically collect 5-8 ml of blood by venipuncture. Allow the blood to clot at room temperature (20-25°C) before separating serum to avoid hemolysis which could interfere with test results. Specimens should be stored refrigerated at 2-8°C and tested within one week of collection. Long term storage should be at -20°C in aliquots to avoid repeated freezing and thawing. Do not store in self-defrosting freezer.

Avoid using contaminated sera as they may contain proteolytic enzymes which will digest the substrate. It is unnecessary to heat inactivate serum specimens prior to testing; however, sera that have been heat inactivated may be used.

When testing paired samples to look for evidence of recent infection, the acute specimen should be obtained as soon as possible after onset of illness and the convalescent specimen obtained 7-14 days later. Acute and convalescent specimens must be tested simultaneously, in the same assay, looking for a significant change in antibody titer between the paired sera. If the first specimen is obtained too late during the course of the infection, a significant rise in the antibody titer may not be detected.

**TEST PROCEDURE**

1. **SPECIMEN PREPARATION**

   **Screening:**
   Prepare a 1:10 dilution of each patient’s serum by adding 0.05 ml (50 µl) of patient’s serum to 0.45 ml of PBS.

   **Semi-quantitation:**
   Serum dilutions are utilized to measure antibody titer. Each laboratory should establish its own titrating protocol; however, the following fourfold serial titration suggested:

   a. Prepare a 1:10 dilution of each patient’s serum by adding 0.05 ml (50 µl) of patient’s serum to 0.45 ml of PBS in tube #1.

   b. Add 0.3 ml PBS to tubes #2, #3, #4 and #5.

c. Using a 100 µl pipette, transfer 0.1 ml (100 µl) from tube #1 to tube #2. Mix. Using a new tip for each dilution, transfer 0.1 ml (100 µl) from the second tube to the third, from the third tube to the fourth, and from the fourth tube to the fifth, mixing after each transfer. This will give a fourfold titration with the following dilutions:

   - Tube #1 = 1:10
   - Tube #2 = 1:40
   - Tube #3 = 1:160
   - Tube #4 = 1:640
   - Tube #5 = 1:2560

**MATERIALS PROVIDED**

1. Mumps Virus Antigen Substrate Slides
2. Fluorescent Antibody Conjugate
3. Positive Control Serum
4. Negative Control Serum
5. Phosphate Buffered Saline (PBS)
6. Mounting Medium

**MATERIALS REQUIRED BUT NOT PROVIDED**

1. One liter volumetric flask or one liter graduated cylinder
2. Distilled water - CAP Type one or equivalent
3. One-liter screw capped container
4. Disposable test tubes (12 x 75 mm or comparable) and rack
5. Disposable serological pipettes
6. Calibrated pipettes to deliver 50 µl, 100 µl and 200 µl, with disposable pipette tips
7. Pasteur pipettes and bulbs
8. Moist chambers
9. Plastic squeeze wash bottle
10. Coplin jars or staining dishes with slide racks
11. 24 x 60 mm #1 coverslips
12. Felt tip marking pen
13. Fluorescence microscope equipped with a mercury or tungsten-halogen light source, a 390-490nm excitation filter and 515-520nm barrier filter, and optics to give a total magnification of 200X or 250X. The excitation wavelength of FITC is 490nm and the emission wavelength is 520nm.
TEST PROCEDURE (continued)

2. SLIDE PREPARATION
   Remove reagents and as many slides as are required from
   the refrigerator or freezer and allow to equilibrate to room
   temperature (20-25°C) for at least 5 minutes. Remove
   slides from sealed foil pouches being careful not to touch
   the antigen surface. Identify each slide using a felt tip marking
   pen.

3. SPECIMEN APPLICATION
   Using separate Pasteur pipettes, apply one drop (20-30 µl)
   of the Positive Control, one drop (20-30 µl) of the Negative
   Control, and one drop (20-30 µl) of each patient serum
   dilution to individual wells of the slide. Do not touch the
   antigen surface with the pipette while dropping. Do not
   allow drops to mix, as cross contamination of samples
   between wells could cause erroneous results.

4. INCUBATION 1
   Incubate in a moist chamber at room temperature
   (20-25°C) for 30 minutes.

   NOTE: THE ANTIGEN MUST NOT BE
   ALLOWED TO DRY DURING ANY OF THE
   FOLLOWING STEPS. Nonspecific binding may
   occur if the reagent is allowed to dry on the
   slide.

5. RINSE 1
   Remove slides from moist chamber and rinse GENTLY
   with PBS using a squeeze wash bottle. Do not focus the
   PBS stream directly onto the wells. To prevent cross
   contamination tilt slide first toward wells 1-6 and,
   running a PBS stream along the midline of the slide, allow
   the PBS to run off the top edge of the slide. Then, tilt the
   slide toward wells 7-12 and repeat this procedure,
   allowing the PBS to run off the bottom edge of the slide.
   For six well slides, tilt slide down and run the PBS stream
   across the slide above the wells, allowing the PBS to run
   off the bottom edge of the slide.

6. WASH 1
   Place slides in Coplin jars or staining dishes and wash in
   two changes of PBS for not less than five minutes or
   more than ten minutes each, agitating gently at entry and
   prior to removal.

7. CONJUGATE APPLICATION
   Remove slides from the wash one at a time, shake off
   excess PBS, dry around outside edges if necessary and return
   each slide to the moist chamber. Apply one drop of
   conjugate to each well of each slide, making sure each
   well is completely covered.

8. INCUBATION 2
   Incubate in a moist chamber at room temperature (20-25°C)
   for 30 minutes. Protect slides from excessive light.

9. RINSE 2
   Remove slides from moist chamber and rinse GENTLY
   with PBS using a squeeze wash bottle. As suggested in
   step 5., do not focus PBS stream directly onto the wells.

10. WASH 2
    Place slides in Coplin jars or staining dishes and wash in
    two changes of PBS for not less than five minutes or
    more than ten minutes each, agitating gently at entry and
    prior to removal.

11. COVERSILP
    Remove slides one at a time from last PBS wash, shake
    off excess PBS and immediately add two to four drops of
    mounting medium across the slide. Tilt slide and rest the
    edge of the coverslip against the bottom of the slide
    allowing the mounting medium to form a continuous
    bead between the coverslip and slide. Gently lower the
    coverslip from the bottom of the slide to the top, being
    careful to avoid air bubbles. Drain excess mounting
    medium by holding the edge of the slide against absorbent
    paper. Wipe off back of slide.

12. READ
    Examine stained slides as soon as possible using a
    properly equipped fluorescence microscope. It is
    recommended that slides be examined on the same day as
    they are stained. If any delay is anticipated, store slides
    in the refrigerator (2-8°C) away from direct light and read
    the following day. Do not allow mounting medium to dry
    between slide and coverslip. If drying should occur, add
    additional mounting medium or recoverslip slide.

FLUORESCENT INTENSITY GRADING
Fluorescent intensity may be semi-quantitated by
following the guidelines established by the Centers for
Disease Control, Atlanta, Georgia.8

   4+ = Maximal fluorescence; brilliant yellow-green.
   3+ = Less brilliant yellow-green fluorescence.
   2+ = Definite but dull yellow-green fluorescence.
   1+ = Very dim subdued fluorescence.

The degree of fluorescent intensity is not clinically
relevant and has only limited value as an indicator of
titer. Differences in fluorescence microscope optics,
filters and light sources may result in differences of 1+ or
more fluorescent intensity when observing the same slide
using different microscopes.
QUALITY CONTROL

SPECIFICITY CONTROL
Both a positive and negative antibody control must be included with each run. These controls must be examined prior to reading test samples and should demonstrate the following results:

Negative Control
Using the MBL Bion MUMPS NEGATIVE CONTROL SERUM as provided with the MBL Bion MUMPS-G ANTIBODY TEST SYSTEM, the infected cells should exhibit less than 1+ fluorescence and appear reddish-orange due to the counterstain.

Positive Control
Using the MBL Bion MUMPS POSITIVE IgG CONTROL SERUM as provided with the MBL Bion MUMPS-G ANTIBODY TEST SYSTEM, Mumps infected cells should exhibit well defined specific fluorescent staining at an intensity of 3+, or greater. The Mumps Virus fluorescent staining pattern consists of fine and coarse cytoplasmic particles in cells that maintain their individuality of size and shape. Approximately 10-50% of the cells should exhibit this specific staining pattern with the uninfected cells staining reddish-orange due to the counterstain.

SENSITIVITY CONTROL
A titered control included with each run tests substrate sensitivity, as well as, checks technique, conjugate quality and the microscope optical system. The endpoint titer of each lot of MBL Bion MUMPS POSITIVE IgG CONTROL SERUM must be determined. There must not be more than a twofold difference (+/-) in titer from the stated endpoint. Each run should include the endpoint dilution, one fourfold dilution above and one fourfold dilution below the endpoint dilution. The more concentrated dilution should be positive and the less concentrated dilution negative. If the control does not behave as described, the test results are invalid and the tests should be repeated. If the control again fails to show the proper reaction upon repeat testing, do not report the test results.

READING OF TEST RESULTS

NEGATIVE
A serum dilution is considered negative for Mumps IgG antibodies if the cells exhibit less than 1+ fluorescence and appear reddish-orange due to the counterstain, or if the fluorescence observed is not the specific staining pattern of Mumps Virus.

A sample is considered negative for Mumps IgG antibodies if it exhibits less than 1+ fluorescence at a serum dilution of 1:10 and all greater dilutions, or if the fluorescence observed is not the specific staining pattern of Mumps Virus.

... Negative samples may exhibit fluorescent staining of the infected cells slightly greater than the Negative Control, but less than 1+.

... Nonspecific staining of all cells observed in some sera at low dilutions is most likely due to the presence of autoantibodies against cellular components in either the nucleus or cytoplasm.

... Staining of areas other than the viral infected cells should be interpreted as negative and attention should be directed to specific steps in the staining method (e.g., RINSE and WASH steps).

POSITIVE
A serum dilution is considered positive for Mumps IgG antibodies if, at an intensity of 1+ or greater, there is well defined specific fluorescent staining in the Mumps Virus infected cells. The Mumps Virus fluorescent staining pattern consists of fine and coarse cytoplasmic particles in cells that maintain their individuality of size and shape. This pattern is exhibited in 10-50% of the cells with the remaining uninfected cells staining reddish-orange due to the counterstain. The number of cells exhibiting a positive staining reaction and the type of fluorescent staining pattern should closely approximate that seen in the Positive Control.

A sample is considered positive for Mumps IgG antibodies if it exhibits the characteristic Mumps Virus staining pattern with a fluorescent intensity of 1+ or greater at a serum dilution of 1:10 or greater.

NOTE: Each field should contain cells that exhibit no apple-green fluorescence. Should most of the cells in the patient test wells fluoresce apple-green in the nucleus and/or cytoplasm, an autoimmune staining reaction due to the presence of autoantibodies should be considered.9,10 It is recommended that such samples be diluted beyond the interference for better interpretation. It is possible that autoantibody staining may mask specific staining such that an interpretation cannot be made. Should this occur, test results should be reported as “Unable to interpret due to the presence of interfering antibodies.”

TITRATION
If a semi-quantitative titration is performed, the result should be reported as the reciprocal of the last dilution in which 1+ apple-green fluorescent intensity of the specific staining pattern is detected. When reading fourfold serial dilutions, endpoints can be extrapolated where necessary.

EXAMPLE OF ENDPOINT EXTRAPOLATION:

<td>2. a past experience with Mumps Virus and usually indicates immunity;</td>
</tr>
<tr>
<td></td>
<td>3. a passively acquired antibody from recent blood transfusions, organ transplantation or transplacental transfer.</td>
</tr>
</tbody>
</table>

**NOTE:** The titer of a single specimen should not be the only criteria used to aid in the diagnosis of primary Mumps infections. Paired samples (acute and convalescent) must be collected and tested simultaneously in the same assay to look for a seroconversion or a significant rise in titer. When only a single specimen is available, testing for IgM specific Mumps Virus antibodies may help to confirm a diagnosis of active Mumps Virus infection.

</tbody>
</table>
LIMITATIONS OF THE PROCEDURE

1. Mumps Virus IgG antibody test results should be used in conjunction with information available from clinical evaluation and other diagnostic information.
2. A single serological IgG antibody titer to Mumps should not be used as the only criterion for diagnosis. Paired serum samples (acute and convalescent) and testing for IgM specific Mumps antibodies may provide more meaningful data.
3. A negative test result does not necessarily rule out current or recent infection. The specimen may have been collected too early in the disease before demonstrable antibody is present.
4. Lack of significant rise in titer does not exclude the possibility of recent infection but may indicate an acute phase specimen was obtained too late.
5. Positive test results from cord blood or neonates should be interpreted with caution. The presence of IgG antibody in cord blood is usually the result of passive transfer from mother to the fetus. A negative test, however, may be useful in excluding possible infection.11
6. Test results on specimens from immunosuppressed patients and pregnant women may be difficult to interpret.
7. Positive test results may not be valid in persons who have received blood transfusions or various blood products within the past several months.
8. Antinuclear antibodies (ANA) present in serum may interfere with the Mumps IFA test. They can be differentiated from Mumps staining in that ANAs stain the nuclei in all cells; whereas, Mumps antibodies exhibit staining in only the 10-50% infected cells.8
9. Cytoplasmic fluorescence in the majority of the cells may be due to the presence of antimitochondrial antibodies (AMA) often seen in primary biliary cirrhosis.10 They can be differentiated from the specific antigen staining in that AMA will stain the cytoplasm of all cells; whereas, Mumps antibodies exhibit staining only in the 10-50% infected cells.
10. Endpoint reactions may vary between laboratories due to differences in type or condition of fluorescence microscope employed, diluting apparatus, as well as the experience level of personnel performing the assay.
11. If both the positive and negative control substrate cells are not visible when viewed using the fluorescence microscope, it may be necessary to replace or realign the light source and check the specific filters.
12. Cell culture substrate slides may exhibit nonspecific fluorescence due to contamination of antibodies or PBS rinse-wash solutions with bacteria or fungi. It is very important that personnel reading the staining results have experience in fluorescence microscopy.
13. The CDC and FDA jointly determined that the MBL Bion MUMPS-G ANTIBODY TEST SYSTEM falls in the High Complexity category. Thus laboratories performing this test are subject to specific laboratory standards pertaining to certification by CLIA 1988 regulations.

SPECIFIC LIMITATIONS OF THE MUMPS VIRUS ASSAY

Mumps and Parainfluenza Viruses share common antigens, and serologic cross-reactions are possible. Therefore, a positive result may not always mean immunity to the virus that is being evaluated.12 Cases have been reported where individuals with serologic evidence of immunity have subsequently developed mumps.13 Cross-reactions might account for these occasional reported instances of reinfection.3 However, this serologic evidence is based primarily upon complement fixation assay systems; whereas, testing by immunofluorescence does not appear to have this problem of cross-reactions.1,2,4,14

EXPECTED VALUES

The medical literature indicates that approximately one-third of Mumps Virus infections are subclinical or silent in clinical presentation. Many adults fail to identify the fact that they have had Mumps even though laboratory studies indicate a previous infection.12 Only 5% of the adult households studied lack detectable Mumps antibody although many more reported a negative medical history. Evaluation of a group of medical students revealed the fact that 88% reporting no prior history of Mumps were found to have antibody to the virus.2

SPECIFIC PERFORMANCE CHARACTERISTICS

Relative specificity and sensitivity evaluations of the MBL Bion MUMPS-G ANTIBODY TEST SYSTEM were conducted on a broad range of patient serum samples. These serum specimens were tested in comparison with another commercially available Mumps IgG Antibody IFA test system for the presence of IgG antibodies to Mumps Virus.

As summarized in TABLE 1, of the one hundred twenty-one serum specimens compared qualitatively, one hundred two were positive and fifteen were negative with both systems. Of the four specimens which could not be interpreted with either system, three were contaminated digesting off the antigen and one had interfering nonspecific staining. There was complete agreement between the two systems with no sera vacillating between a positive or negative result.14

Twenty-four serum specimens ranging in titer from less than 1:10 to 10,240 were compared semi-quantitatively. Eight specimens were negative with both systems and twelve specimens were positive with both systems. The endpoint of one strongly positive introduction of the live, attenuated Mumps vaccine in 1967 resulted in the detection of measurable antibody in more than 90% of the recipients of the vaccine. However, antibody titers are lower than those observed after a natural Mumps infection.19

A study of 38 normal sera from the Midwestern United States using the MBL Bion MUMPS-G ANTIBODY TEST SYSTEM provided information regarding normal adult IgG antibody titers. The titers ranged from less than 1:10 (5%) to 1:320 (8%). The majority of samples evaluated fell between 1.20 and 1.80 (76%).14
Interlaboratory precision of the MBL Bion MUMPS-G ANTIBODY TEST SYSTEM was evaluated by testing twenty-four serum specimens (8 negative and 16 positive over a range of titers). Three different manufacturing lots were tested; and, a single lot was tested in triplicate. In each instance there was no more than a twofold difference (+/-) in titer between any of the comparisons, which is within the confidence limits of this methodology. None of the test sera vacillated between a positive or a negative result.

The Immunofluorescent Antibody Assay (IFA) is more sensitive than the traditional Complement Fixation (CF) test in the detection of antibody to Mumps Virus, which allows for the determination of immune status. In a study of 32 serum samples, there was 84% overall agreement between the two procedures with five samples positive by IFA and negative by CF suggesting an increased sensitivity of the IFA procedure. The results are summarized in Table 3.13

IFA has an additional advantage over CF by its capability of allowing for separate identification of specific IgG and IgM antibodies. This allows for the diagnosis of acute infection with a single specimen (IgM), as well as, by a fourfold rise in titer (IgG and IgM) between acute and convalescent specimens. Performing both the IgG and IgM tests provides the physician with a more useful complete picture of the patient’s immunological status.

Table 4 summarizes the CF and IFA results on several paired serum specimens. A fourfold, or greater, rise in titer by the CF test for all five sets of paired specimens indicates a serological diagnosis of Mumps Virus infection. With the IFA tests, four of the patients with positive IgM results already on their acute specimens could have been diagnosed immediately without waiting for the convalescent specimen. Diagnosis of the fifth patient required testing both acute and convalescent specimens for a significant rise in titer. With the IgG test alone, three patients could be diagnosed with recent Mumps infection based on a fourfold, or greater, rise in titer between paired samples. However, without the accompanying positive IgM results, two patients with equally high IgG titers on both acute and convalescent specimens showed no clear-cut evidence of recent infection. In these cases, testing for specific IgM specific Mumps antibodies was necessary to confirm the diagnosis.

The Mumps Virus is a member of the Paramyxovirus Group. A study was performed to insure that no cross-reactions occurred between antibodies specific for the Parainfluenza members and the Mumps antigen in the MBL Bion MUMPS-G ANTIBODY TEST SYSTEM. Eleven of the twelve sera tested had antibodies to Parainfluenza types 1, 2, and/or 3. There was one specimen negative for all three antibodies. All sera evaluated were negative when tested on the BION Mumps antigen substrate. Therefore, false positive reactions for Mumps Virus antibody will most likely not be obtained due to exposure to the Parainfluenza Viruses.

Table 5 - Summary of Paramyxovirus Group Specificity Study
